**Working Principle:** The working of solar cells involves light photons creating electron-hole pairs at the p-n junction, generating a voltage capable of driving a current across a connected load.

Have you decided to install your own photovoltaic system but don't know where to start? We have produced a number of connection diagrams for the various components of a solar photovoltaic system.

Overview Working explanation Photogeneration of charge carriers The p-n junction Charge carrier separation Connection to an external load Equivalent circuit of a solar cell 1. Photons in sunlight hit the solar panel and are absorbed by semi-conducting materials. 2. Electrons (negatively charged) are knocked loose from their atoms as they are excited. Due to their special structure and the materials in solar cells, the electrons are only allowed to move in a single direction. The electronic structure of the materials is very important for the process to work, and often silicon incorporating small amounts of boron or phosphorus is used in different layers.

In general, a solar cell structure consists of an absorber layer, in which the photons of an incident radiation are efficiently absorbed resulting in a creation of electron-hole pairs.
